

Approximation Algorithm

An approximation algorithm is the way of dealing with NP-completeness for optimization problems.

The goal of approximation algorithm is to give solution closer to optimal solution in polynomial time.

$C \rightarrow$ cost of solution given by Approximation Sol.
 $C^* \rightarrow$ cost of optimal solution
 $P(n) \rightarrow$ Approximation Ratio
 $n \rightarrow$ input size

① Maximization: $\frac{C^*}{C} \leq P(n)$

② Minimization: $\frac{C}{C^*} \leq P(n) : P(n) \neq 1$

Vertex Cover Problem

A vertex cover of a graph G is a subset of vertices which cover every edges.

So, vertex cover problem is the minimum size vertex cover.

$$\begin{aligned}\text{vertex cover} &= \{1, 2, 2, 5\} \\ &= \{5, 6, 2, 1\} \\ &= \{2, 3, 5\} \leftarrow \underline{\underline{\text{min}}} \\ &\quad \checkmark\end{aligned}$$

Approximation - Vertex Cover (G)

1. $C \leftarrow \emptyset$
2. $E' \leftarrow E(G)$
3. while $E' \neq \emptyset$
do let (u, v) an arbitrary
edge in E'
4. $C \leftarrow C \cup \{u, v\}$
5. Remove from E' every
edge incident either on
 u or v .
- 6 return C .

$$E' = \{(\overset{\times}{a}, \overset{\times}{b}), (\overset{\checkmark}{b}, \overset{\checkmark}{c}), (\overset{\times}{c}, \overset{\times}{d}), (\overset{\times}{c}, \overset{\times}{e}), (\overset{\times}{d}, \overset{\times}{e}), (\overset{\times}{d}, \overset{\times}{f}), (\overset{\checkmark}{e}, \overset{\checkmark}{f}), (\overset{\checkmark}{d}, \overset{\checkmark}{g})\}$$

$$\begin{aligned} C &= \phi \\ &= \phi \cup \{b, c\} \\ &= \{b, c\} \\ &= \{b, c\} \cup \{e, f\} \\ &= \{b, c, e, f\} \end{aligned}$$

$$\left. \begin{aligned} C &= \{b, c, e, f\} \cup \{d, g\} \\ &= \{b, c, e, f, d, g\} \end{aligned} \right\} \begin{aligned} &\text{Ass} \\ &\uparrow \text{Approximation algo.} \Rightarrow C \\ &\downarrow \\ &6 \text{ vertices } \checkmark \end{aligned}$$

but the optimal solution for above graph G is

$C^* \rightarrow \{b, d, e\}$ i.e 3 vertices.

$$\therefore \text{Minimization} = \frac{C}{C^*}$$

$$= \frac{6}{3} = 2 > 1$$

$\rightarrow P(n) \checkmark$

Randomized Algorithm

An algorithm that uses random number to decide what to do next anywhere in its logic called the Randomized Algorithm.

✓ this algorithm is used to reduce space and time complexity.

① Las Vegas Algo

- output is always correct.

e.g. Randomized Quick Sort

e.g. `AlgoSearch Repeat(A)`
 `{`
 `for (i=0; i ≤ n-1; i++)`
 `{`
 `for (j=i+1; j ≤ n; j++)`
 `{`
 `if (A[i] == A[j])`
 `return True`
 `}`
 `}`
 `}`

`AlgoSearch Repeat-LV(A)`

`{`
 `while (True) do`
 `i = random() mod n+1`
 `j = random() mod n+1`
 `if ((i ≠ j) and (A[i] == A[j]))`
 `return True`
 `}`

② Monte Carlo Algo

- output may be incorrect

e.g. Randomized median

e.g. `AlgoSearch (A, k)`
 `{`
 `for (i=0; i ≤ n-1; i++)`
 `{`
 `if (A[i] == k)`
 `return True`
 `}`
 `}`

`Algo Monte Carlo Search (A, k, n)`

`{`
 `for (i=0; i ≤ n; i++)`
 `{`
 `j = random() mod n+1`
 `if (A[j] == k)`
 `return True`
 `}`
 `}`
